

Comments on the XML file and its edits:

From the Zehr2017.arb file, data was exported in XML format. In order to reformat for dada2's assign taxonomy function, each sequence should have the following taxonomic information (where known).

Domain; Phylum; Class; Order; Family; Genus

If some of the taxonomic levels are unknown, they can be left blank. For example, the taxonomy of "Bacteroidales bacterium Barb6XT" (acc: OAV67900.1) is only known to the Order rank.

Bacteria; Bacteroidetes; Bacteroidia; Bacteroidales;

The taxonomy cannot skip ranks. If the genus is known but the family is unknown, as in *Desulfuribacillus alkaliarsenatis* (OEF96273.1), it's taxonomy would be:

Bacteria; Firmicutes; Bacilli; Bacillales; Bacillales incertae sedis; Desulfuribacillus

In the XML file, each parent node (<species>) contains the taxonomy (<tax>) and sequence (<data>) as child nodes. The text proceeding the taxonomy should match the "full_taxon_name" entry exactly, as this is used in the fasta generating script to remove the text proceeding the taxonomy. Only exact matches are removed. For example, for "Crocospaera watsonii WH 0401", the exact text found in its "full_taxon_name" proceeds the start of the taxonomy.

<full_taxon_name>**Crocospaera watsonii WH 0401**</full_taxon_name>

<tax>**Crocospaera watsonii WH 0401** Bacteria; Cyanobacteria; Cyanophyceae; Chroococcales; Aphanothecaceae; Crocospaera

Documentation:

The details below document changes that were made to the original XML file generated from Zehr2017.arb. Some changes are solely to facilitate the dada2 database generation (e.g. removing subclass, groups, complexes or adding missing taxonomic ranks), and other changes are updates or corrections to the taxonomy based on the NCBI database for associated accession number. Changes are grouped by taxonomy.
